Camp, eds. *Gulf of Mexico: Its Origins, Waters, and Biota. I. Biodiversity*, pp. 187-259. Texas A&M Univ. Press.

## Seaweeds of the Gulf of Mexico

Suzanne Fredericq, Tae Oh Cho, Sylvia A. Earle, Carlos Frederico Gurgel, David M. Krayesky, Luz Elena Mateo-Cid, A. Catalina Mendoza-González, James N. Norris, and Ana María Suárez

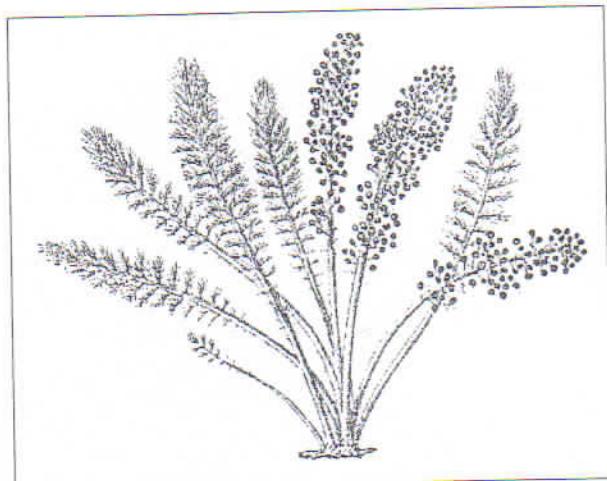

The marine macroalgae, or seaweeds, are a heterogenous group historically lumped together as “Protists,” an assemblage of taxa whose members typically lack true roots, shoots, leaves, seeds, or water-conducting tissues. They comprise the multicellular green algae (Chlorophyta), red algae (Rhodophyta), and brown algae (Phaeophyceae). Until very recently, the relationship among the Algae and other Protists remained inconclusive and often contradictory (Adl et al. 2005).

Our understanding of algal phylogeny has dramatically increased with molecular evolutionary methods, and the latest research indicates that the Rhodophyta is a distinct eukaryotic lineage that shares a most common ancestry with the Chlorophyta in the Plant lineage (Oliveira and Bhattacharya 2000). A second cluster, the Chromalveolata, comprises the Stramenopiles, in which the brown algae belong, in addition to diatoms, many zoosporic fungi, and the opalinids, among others (Palmer 2000, Adl et al. 2005). Of the three seaweed groups, the red algae are unique in the Tree of Life in that they share a suite of characters that do not occur together in any other eukaryote, namely, a complete lack of flagellated stages including absence of centrioles, flagellar basal bodies, or other 9+2 structures (Adl et al. 2005). The seaweeds exhibit a broad variety of morphologies and life histories. Unlike green plants, animals, and even brown algae, red algae have attained this diversity without having evolved true tissue differentiation (Hommersand and Fredericq 1990). The molecular and biochemical mechanisms of their development remain largely unexplored.

A green seaweed, *Acetabularia*. After Taylor 1954.

The classification within the Rhodophyta at the ordinal level is unstable and in a constant flux, more so than in the Chlorophyta and the Phaeophyceae, and it is currently undergoing much taxonomic revision that has led to proposals of new and recircumscribed orders (Adl et al. 2005). As misinterpretations of superficial similarities have resulted in erroneous systems of classification at a variety of taxonomic levels, molecular-based phylogenies in the red, brown, and green algae each provide an independent test of classification to the one based on morphological or ultrastructural evidence. Besides elucidating relationships, phylogenetic hypotheses inferred from gene sequence data provide the critical framework for studies of morphological character evolution and life history evolution. Hence, as is the case for other taxa previously referred to as “Protists,” we have here opted to follow a hierarchical system of listing the taxa from the Gulf of

A green seaweed, *Batophora*. After Børgesen 1913.

Mexico without formal rank designations, such as “class,” “subclass,” “super-order,” or “order”; this approach is currently the preferred decision primarily motivated by utility, to avoid the common problem of a single change causing a cascade of changes to the system (Adl et al. 2005).

There are 10,000–20,000 accepted species names of seaweeds worldwide (Woelkerling 1990, Norton, Melkonian, and Andersen 1996, Guiry and Guiry 2007). There are about 5900 validly accepted species of red algae; of these, only 3 percent are freshwater. There are about 1600 species of marine green algae and 1800 species of brown algae listed in AlgaeBase (Guiry and Guiry 2007). Seaweeds are most common on hard-bottom habitats in marine environments, growing as epiphytes on other algae, seagrasses, or mangrove roots, epizoic on animals, epilithic on pebbles or rocky substrata, psammophilic in sand, or pelagic and drifting (Lüning 1990). They occur at all latitudes from the Arctic to the Antarctic and occupy the entire range of depths inhabitable by photosynthetic organisms, from high intertidal regions to subtidal depths as great as 268 m (San Salvador I., Bahamas, is the greatest depth for known plant life) (Littler et al. 1985).

Historically, the seaweeds were defined as taxonomic groups based on their pigmentation. The red color in the red algae is due to the presence of phycoerythrin that reflects red light, absorbs blue light, and masks the green chlorophyll *a* (Gantt 1990). The color varies according to the ratio of phycoerythrin to phycocyanin and may appear green or bluish from the chlorophyll and other masking pigments. Because blue light penetrates water to a greater depth than light of longer wavelengths, these pigments allow red algae to photosynthesize and live at somewhat greater depths than most other algae (Ramus

1978). Green and brown algae lack phycoerythrin, and brown algae contain chlorophyll *c* in addition to chl *a*. In addition, the red, brown, and green seaweeds contain a suite of additional secondary pigments (Lobban and Harrison 1994).

The cell walls of red algae consist of cellulosic fibers embedded in a matrix of nonfibrillar materials, the phycocolloids. The most abundant of these polysaccharides are referred to either as agars or carrageenans, and they are of economic importance (Abbott 1996). Agar finds its widest use as a solid microbiological culture substratum and in a range of laboratory applications. It is not used for nutritional value in food, but rather as an emulsifier as a pectin in preserves; as a clarifying agent in the production of beer, wine, and coffee; and in the cosmetic and medical industries (Zemke-White and Ohno 1999). Agarophytes that produce high-quality agar are found in the Gelidaceae and Gracilariaeae (Craigie 1990).

Carrageenans are used by the food industry as texture modifiers because of their high viscosity and gelling properties (Santos 1989, De Ruiter and Rudolph 1997). It is the gelling-strength, *kappa*-type carrageenans that are much sought after by the phycocolloid industry (Knutsen et al. 1994). Current markets for kappa carrageenan are concentrated in the food, dentifrice, pharmaceutical, and cosmetics industries (Kapraun 1999). Economically important carageenophytes are members of the Gigartinaceae-complex and the Solieriaceae-complex (McCandless 1978, Doty and Norris 1985). More and more, chemists are discovering that cell wall composition is highly correlated with revised systematic concepts at every taxonomic level, and recent papers deal with the integration of polysaccharide chemistry, anatomical features, and DNA sequences (Usov 1992, Liao et al. 1993, Chiovitti et al. 1995, 2001, Fredericq, Hommersand, and Freshwater 1996, Fredericq, Freshwater, and Hommersand 1999, Chopin, Kerin, and Mazerolle 1999). Alginates are extracted from the cell walls of brown algae (Chapman and Chapman 1980).

Antiviral and anticoagulant properties of the insoluble polysaccharide fraction have been reported, which suggest promising antiherpetic activity (Caceres et al. 2000, Lee et al. 2004). In Asia, seaweeds are important sources of food with a high vitamin and protein content, such as nori (Oohusa 1993). Many red algae metabolize polyunsaturated fatty acids to oxidized products resembling the eicosanoid hormones from mammals (Wise et al. 1996). Because of their biological properties, seaweed-derived oxylipins have potential utility as pharmaceutical

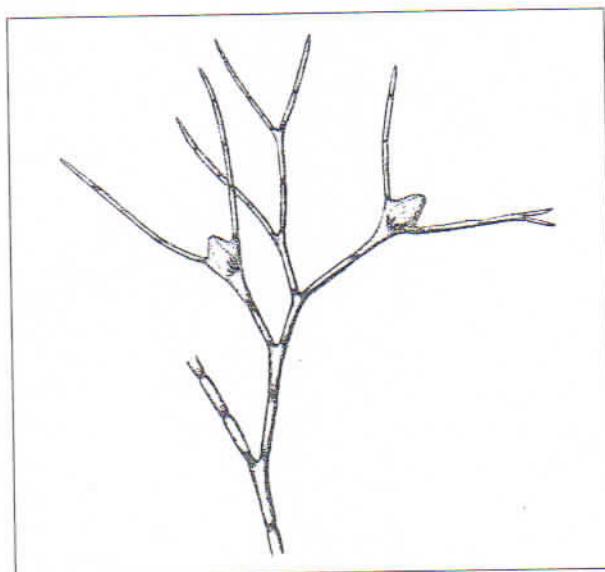

and research biochemicals (Gerwick et al. 1993, Fenical 1997).

Some seaweed species reproduce by vegetative fragmentation (Hernandez-Gonzalez et al. 2007) or spore formation, but most undergo a complex life cycle involving an alternation of generations. It was only after culture methods were introduced (von Stosch 1965) that it was finally verified that in most red algae there is a fundamental linkage of the sexual system and a life history consisting of three phases (Hawkes 1990). It has been argued that selection has favored the evolution of a triphasic life history in red algae as a compensation for an inefficient fertilization in the absence of motile gametes (Searles 1980, Maggs 1988). The comparative morphology of the great diversity of postfertilization fruiting body types, ranging from simple to very complex, has traditionally formed the basis for the classification of red algae (Kylin 1956, Hommersand and Fredericq 1990).

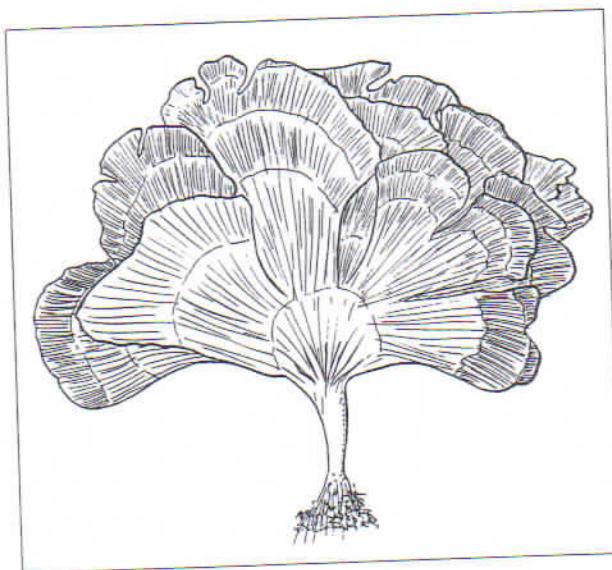

Calcareous algae have long been recognized as predominant contributors to both the bulk and frame structures of the majority of reef limestone deposits. Some of the adaptive advantages of calcification in reef algae include mechanical support and minimization of damage from sand scour, wave shock, and herbivory, as well as reduction of fouling epiphytes (Littler et al. 2006). Few reefs are dominated solely by corals, hence the term "coral" reef is often a misnomer and calcareous coralline red algae generally exceed corals in importance as reef-building organisms, as they are the principal cementing agents of nearly all tropical reefs. Use of the terms tropical reefs or biotic reefs is often preferred when referring to these complex marine structures (Littler, Littler, and Taylor 1995). Without certain species of crustose corallines or peyssonnelioid red algae, most reefs would not exist. Algal structure is harder than most corals, and this durability enables them to withstand the tremendous power of the huge breakers on oceanic islands. Within such extreme high-energy systems, coralline algae form an algal ridge that absorbs wave energy, and hence protects the more delicate corals, fleshy algae, sponges, and other organisms (Adey 1998). Reef-building corallines are able to grow at greater depths in weaker light than other primary producers (Littler and Littler 2007). Deeper sand plains often contain isolated rubble fragments and unattached forms of coralline algae or rhodoliths that provide suitable substrata for a host of fleshy seaweeds. These rhodoliths are harvested as maerl in western Europe (Blake and Maggs 2003).

Where herbivory is reduced, or due to excess nutrient

increases and other stresses, biotic reefs shift from coral to fleshy macroalgal-dominated communities with high gross and net primary productivities (Miller and Hay 1996, Morand and Brian 1996). In this state, production of a calcified framework is low, and as a result of constant carbonate bioerosion, the reef begins to degenerate to a more-or-less flat pavement. The transformation represents serious environmental degradation, with the delicate balance between nutrients, grazing, and reef community structure extensively studied in the past decades (Littler and Littler 2007). Whereas frondose macroalgae normally are rare on reefs because of intense grazing pressure by herbivorous fishes, mollusks, crustaceans, and sea urchins, sparse mats of fast-growing, opportunistic filamentous red and green algae and algal turfs usually are responsible for the very high primary productivity per unit area (Burkepile and Hay 2006). By their scraping mode of feeding, herbivorous fishes continuously provide new substrata and thereby select for opportunistic taxa, as well as long-lived, scrape-tolerant coralline algae (Dethier and Steneck 2001). Some algae that are not excessively tough are nonetheless inedible to herbivores, as many contain a variety of potentially distasteful substances such as various halogenated secondary metabolites (Schnitzer et al. 2001). Chemical defenses reach their greatest diversity and frequency in tropical reef habitats, and some genera (*Laurencia*) often are abundant even where grazing is high (Fenical and Norris 1975). Some algae seem to encourage the settlement and metamorphosis of the larvae of a variety of invertebrate grazers (Huggett et al.

A red seaweed, *Jania*. After Børgesen 1920.

A green seaweed, *Udoea*. After Taylor 1954.

2005, Daume 2006). Several herbivorous species of fish maintain “gardens” of green and red algae that, if the animal is removed, are soon consumed by rival herbivores (Ceccarelli, Jones, and McCook 2005). Many seaweeds arise from a basal crust or have a crustose phase in their life history, which are often more resistant to grazing than the erect plants (Dethier and Steneck 2001).

Coralline red algae and green siphonous algae, such as *Halimeda*, are responsible for much of the reef accretion of CaCO<sub>3</sub>, and a major biotic source of reef carbonates for the Pleistocene and Holocene, and sand (Adey 1998). Some thrive on sandy shores, where abrasion and intermittent burial exclude most algae. Their survival is greatly aided by their ability to regenerate following scouring by having incomplete or asexual life histories. When algae of different species are adjacent, one often overgrows the other, and these become constituents of mixed algal turfs (Jompa and McCook 2003, Santelices et al. 2003).

Many algae are sensitive to day length as a trigger for seasonal behavior (Lüning 1990). Growth rates and morphology are influenced greatly by temperature, particularly in saturating irradiance (Pereira, Yarish, and Sousa-Pinto 2006). Temperature is the principal extant controlling factor in geographical distribution behavior (Lüning 1990). One important criterion is the tolerance of extremes, with the upper temperature limit less extreme in subtidal species than in intertidal species, whereas lowered salinities reduce the upper temperature tolerance of many species (Kim and Garbary 2006). Osmotic stress and unfavorable ionic exchange and a shortage of essential metabolites are several ways in which salinity changes

may be important to the survival of seaweeds (Lüning 1990, Adey and Steneck 2001).

Some species thrive in relative calm water sites, others in more turbulent localities (Taylor 1998, Rossi 2006). Moderate water movement is beneficial to seaweeds as it carries a supply of nutrients and gases to the plants, removes waste products, and prevents the settling of silt (Gaylord and Denny 1997). The surface of many algae is mucilaginous, which may reduce skin friction drag (Raven 1992). Among the upright stiff algae are calcareous species in which the risk of breakage is minimized by soft articulations between the calcified segments (Martone 2006).

Most seaweeds are attached to stable rock or animal carapaces or shells (Santelices and Aedo 1999), with rougher substrata enhancing settlement, anchorage, and subsequent survival of the spores. Some that live in calm-water localities are unattached and are drifting (Merceron and Morand 2004). The roughness of the rock surface even on a microscopic scale may be important for some seaweed propagules caught in tiny depressions, and attachment within such depressions also enhances the germlings’ ability to survive water motion (Gaylord et al. 2006). The degree of tolerance to desiccation seems to determine the upper limits of several species of seaweeds on the shore. Mild desiccation might slightly stimulate their photosynthesis, but significant drying usually causes a substantial decline (Lobban and Harrison 1994).

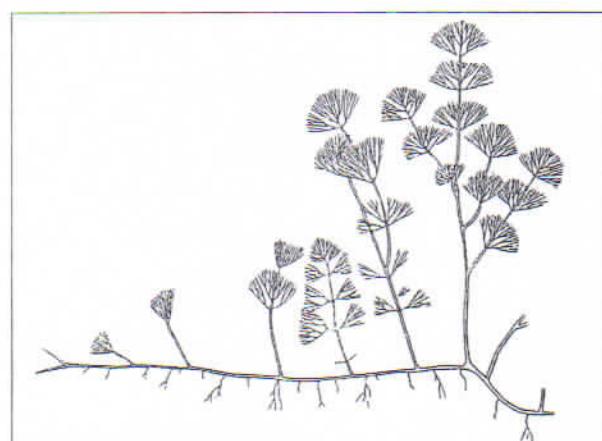

Competition on the shore may be fierce and often sets the lower limits of algal zones (Kim and Garbary 2006). In contrast to the intertidal environment, the influences in the subtidal change fairly gradually within depth, so zonation is not particularly clearcut unless a change in substratum creates a sharp zone (Swanson and Druehl 2000). Temperature limits for reproduction often are narrower than for either growth or survival (Lobban and Harrison 1994). Close to its geographical limit, an alga may lose its power to spread further by means of spores, and vegetative propagation may allow species to persist in the same site at the northern or southern limits of its range (Nováček, Lubbers, and Breeman 1990).

Seagrass leaves appear to be particularly suitable surfaces for algal settlement (Ballantine and Humm 1975, Armitage et al. 2005, Johnson, Heck, and Fourqurean 2006). Except for species of *Syringodium*, seagrass leaves are flat, thus maximizing their photosynthetic surface, diffusion of gases, and nutrient uptake (Dawes 1998, Cornelisen and Thomas 2004). The presence of an epiphytic load on the leaves increases drag and reduces movement

through the water column (Drake, Dobbs, and Zimmerman 2003). In doing so, epiphytes reduce the leaves' ability to remove inorganic nutrients, causing the plant to rely more on absorption of nutrients by roots (Frankovich and Fourqurean 1997). All but one genus of seagrass grows in sandy and silty sediments, usually subtidally, and many red algae, such as *Gracilaria tikvahiae*, frequently lie in loose mats at the base of seagrass leaves in the northeastern (NE) Gulf of Mexico (Dawes 1994).

Macroalgal vegetation is less diverse where siltation is rapid than in places with stable substrata (Karsten et al. 2000). Mangroves roots and the upright pneumatophores emerging from the sediment both support algae (Phillips et al. 1996). Several dominant salt marsh algae show adaptations to extreme environmental conditions, such as desiccation and extreme salinities, and are characterized by ephemeral and often morphologically plastic species (Mathieson and Hehre 1994). Although a few species occasionally lay loose or are embedded in mud, muddy areas are generally inhospitable to red and brown algae in contrast to some green algae (Albrecht 1998).

Introductions of nonindigenous macroalgal species to new ecosystems are a growing concern and one of the major threats to biodiversity and ecosystem function (Schaffelke, Smith, and Hewitt 2006). For example, an aggressive clone of the green alga *Caulerpa taxifolia*, whose origin was traced to a population in Australia (Meusnier et al. 2004), has proved to be highly invasive in the Mediterranean Sea, where the efforts of the governments of France, Spain, Monaco, and Italy have been unable to control its spread.

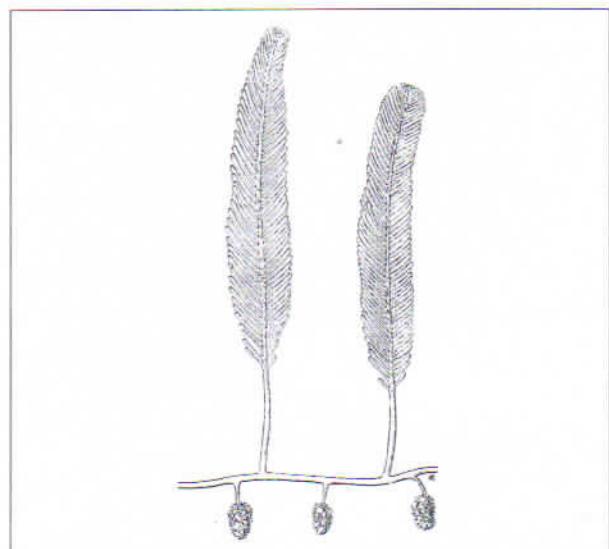

A green seaweed, *Caulerpa*, verticellate species. After Børgesen 1920.

Numerous factors, including eutrophication and introduction of invasive species from ballast water, cause macroalgal blooms (Schaffelke, Smith, and Hewitt 2006). The result of these seaweed blooms can be shading or smothering of other organisms that need sunlight to survive, habitat degradation, and hypoxia as the seaweeds decompose (Lapointe and Bedford 2007). Any type of algal bloom can lead to hypoxia when the algae die and are decomposed by bacteria in the water, with the decomposition process consuming oxygen. Harmful algal blooms (HABs) that produce toxins dangerous to humans and aquatic animals are mostly caused by dinoflagellates and diatoms (Lee et al. 2005), not seaweeds, whereas nontoxic HABs include large blooms of seaweeds that can blanket beaches (Schaffelke, Smith, and Hewitt 2006).

There is no significant fossil record of the evolutionary history of the marine red algae, except for the order Corallinales extending back as far as the Jurassic (Johansen 1981). The oldest taxonomically resolved eukaryote on record, ca. 1200 million years old from Arctic Canada, is identified as a bangiophyte red alga, *Bangiomorpha pubescens*, and marks the onset of a major protistan radiation near the Mesoproterozoic/Neoproterozoic boundary (Butterfield 2000).

In contrast to the Caribbean basin (e.g., Norris and Bucher 1989) and the western Atlantic Ocean as a whole, the Gulf of Mexico historically has been understudied phycologically. Taylor (1954a), in the original list of Bulletin 89 (Galtsoff 1954), listed only 30 species of green algae, 20 species of brown algae, and 28 species of red algae for the entire Gulf of Mexico. Up until the "Hour-glass Cruises" on the West Florida Shelf (Dawes and Van Breedveld 1969), the deepwater seaweeds of the Gulf were

A green seaweed, *Caulerpa*. After Børgesen 1913.

practically unknown, except for the Dry Tortugas, Florida (Taylor 1928). Taylor (1954b) had characterized the flora in the northern part of the Gulf of Mexico as an impoverished tropical Caribbean flora rather than a replacement by a temperate flora, and considered coastal habitats ranging from Galveston, Texas, to Alabama "botanically barren or at least monotonous" (Taylor 1960), due in great part to the high turbidity caused by effluents from the Mississippi, lack of hard substratum in the nearshore intertidal zones, and seasonal fluctuations in salinity and temperature. A major synopsis of the Gulf of Mexico seaweeds since Taylor (1960) was provided by Earle (1972), who synthesized all the records known at the time. In their identification guide to reef plants of the Caribbean, Bahamas, Florida, and Gulf of Mexico, Littler and Littler (2000) included photographic documentation of common taxa from the Gulf. The present paper updates Earle's list by revising the nomenclature and taxonomic placement, and adds many more recently published records, thereby reporting nearly 700 published species and over 70 families of seaweeds from the Gulf (see the taxonomic summary). Many of the algal names listed by Earle (1972) have been placed in synonymy with other taxa; these are listed at the end of this paper (following the checklist of seaweeds).

The Gulf of Mexico is characterized by a relatively shallow but well-developed continental shelf with an extensive system of generally deep, hard, banks of varying origin and composition (Rezak, Bright, and McGrail 1985). Whereas banks of the southern Gulf (below Matagorda Bay, Texas) were typically formed on relict carbonate reefs, upper northwestern mid- and outer-shelf banks originated on unique tectonically created salt domes (Rezak, Bright, and McGrail 1985) along an extensive continental shelf with an average width of about 100 miles. The Flower Garden Banks are deepwater coral habitats in the northwestern Gulf of Mexico and are located on the edge of the outer continental shelf. These bedrock domes overlying uplifted salt domes are capped by an overgrowth of calcareous organisms and represent the largest charted calcareous banks in the northwestern Gulf of Mexico and the northernmost coral reefs on the continental shelf of North America (Bright and Pequegnat 1974). Two mid-shelf northwestern (NW) Gulf hard banks, Stetson Banks and Sonnier Banks, are historically viewed to be largely devoid of algae (Rezak, Bright, and McGrail 1985, Rezak, Gittings, and Bright 1990); however, recent SCUBA collections off these hard banks point to a rich and diverse macroalgal flora (Fredericq, Phillips, and Gavio 2000, Famà et al. 2002, Gavio and Fredericq 2005) and continue

to increase the number of species listed by Rezak, Bright, and McGrail (1985). Published records documenting the offshore presence of deepwater macroalgae in the northwestern Gulf have been even more sparse and restricted to a few hard banks (Eiseman and Blair 1982, Rezak, Bright, and McGrail 1985, Gurgel, Fredericq, and Norris 2004a, Gavio and Fredericq 2005, Gavio, Hickerson, and Fredericq 2005).

The outer shelf West Banks of the Flower Gardens Banks National Marine Sanctuary (NW Gulf), together with the Florida Middle Ground (NE Gulf) represent separate biogeographic extremes in the northward distribution of tropical Atlantic coral reefs or communities dominated by corals (Rezak, Bright, and McGrail 1985). Benthic macroalgae are the dominant biotic components of these communities (Earle 1972, Eiseman and Blair 1982, Gavio, Hickerson, and Fredericq 2005), and deep-water collections conducted in the NW Gulf revealed a greater tropical affinity of the deepwater flora compared to the algae inhabiting the nearshore shallow-water habitats (Kapraun 1974, 1980, Kaldy, Dunton, and Czerny 1995). Seaweeds collected from shallower hard banks are typically small, cryptic, and intermixed, forming small turf or extensive mats less than 1 cm in height and subject to heavy herbivore pressure (Fredericq, Phillips, and Gavio 2000).

Dredged macroalgal collections at depths ranging from 40 m to 90 m conducted offshore the northwestern Gulf and made on unconsolidated rubble banks with box dredges previously employed for the "Hourglass Cruises" (Joyce and Williams 1969) revealed macroalgae that are typically freestanding, leafy, and large, epilithic on loose bedrock or on rhodoliths dominated by crustose coralline red algae. New records of seaweeds dredged offshore of Louisiana have been incorporated in various taxonomic and phylogenetic treatments (e.g., Gavio and Fredericq 2003, 2005, Lin and Fredericq 2003, Gurgel and Fredericq 2004, Gurgel, Fredericq, and Norris 2004a, Gavio, Hickerson, and Fredericq 2005).

The most significant reports of intertidal seaweed species inhabiting the northwestern Gulf off Texas include: Humm and Hildebrand (1962), Edwards (1970, 1976), Edwards and Kapraun (1973), Cowper (1978), Baca, Sorensen, and Cox (1979), Kapraun (1980), Kaldy, Dunton, and Czerny (1995), Kaldy (1996), Lehman (1999), Wardle (1999), and DeYoe and Hockaday (2001); off Louisiana: Humm and Darnell (1959) and Kapraun (1974); and off Mississippi: Humm and Caylor (1957). Deepwater species are listed in Bright and Pequegnat (1974), Eise-

man and Blair (1982), Rezak, Bright, and McGrail (1985), Fredericq, Phillips, and Gavio (2000), Gurgel et al. (2004a, c), Gavio and Fredericq (2003, 2005), and Gavio, Hickerson, and Fredericq (2005).

In the northeastern Gulf, offshore seaweed collections from depths up to 73 m were made during the historic "Hourglass" expedition in the 1960s and reported by Dawes and Van Breedveld (1969) off central West Florida. Dredged collections from the Florida Middle Ground, located on the outer edge of the continental shelf approximately 160 km WNW of Tampa, were also included in Humm and Earle Taylor (1961). The Florida Middle Ground is characterized by discontinuous limestone outcroppings covered with shell, rock, and living and dead corals, with relief of 2–10 m at depths of 25–60 m. Cheney and Dyer (1974) listed 84 species of green, brown, and red seaweeds, and Hopkins et al. (1977) subsequently added 40 new records for the area, increasing the number of macroalgal species to 103; the seaweed flora was characterized as having distinct tropical affinities and undergoing a seasonal pattern of abundance and species diversity, both of which were maximal in the summer (Cheney and Dyer 1974). Deepwater collections conducted in the NW Gulf (Eiseman and Blair 1982) and off East Florida (Hanisak and Blair 1988), and off the NW Atlantic continental shelf in the Carolinas (Searles 1972, 1984a, b, Schneider and Searles 1975, 1976, 1991, Searles and Schneider 1980) revealed a greater tropical affinity of the deepwater flora compared to the algae inhabiting the nearshore shallow-water habitats (e.g., Kapraun 1974 for Louisiana algae). Relevant surveys of seaweeds from the NE Gulf off Florida are listed in Humm (1956), Phillips and Springer (1960), Earle (1969), Humm and Earle Taylor (1961), Dawes et al. (1967), Dawes and Van Breedveld (1969), Croley and Dawes (1970), Dawes (1974), Cheney and Dyer (1974), and Hopkins et al. (1977).

The main treatments for seaweeds in the southwestern (SW) Gulf of Mexico predominantly include a series of studies from the Instituto Polytechnico in Mexico City, pioneered by Laura Huerta, and her students Mendoza-González and Mateo-Cid (e.g., Mateo-Cid and Mendoza-González 1986). The reefs at Cabo Rojo, ~100 km south of Tampico, Mexico, are the closest extensively developed coral reefs in the Gulf of Mexico near the Flower Garden Banks. Marine algae from the Mexican Gulf Coast are listed by Humm and Hildebrand (1962). Regional lists of SW Gulf of Mexico algae include the following: for Tamaulipas—Hildebrand (1957), Garza Barrientos, Martínez Lozano, and Escalante (1984), Zamora

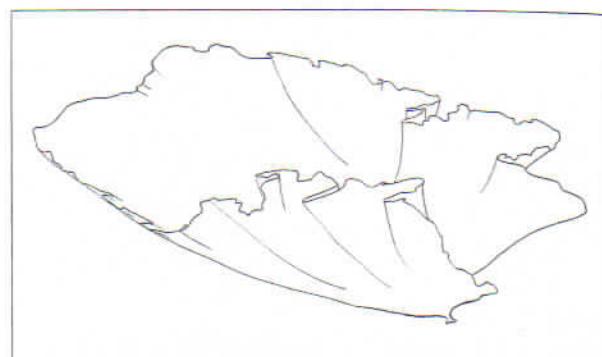

Tovar (1990), Martínez Lozano and Guajardo Ríos (1991), Martínez Lozano and Villarreal Rivera (1991), López Bautista (1992), Martínez Lozano, López Bautista, and Vasquez Martínez (1992), Wynne (1993), López Bautista and Kapraun (1995), and Kapraun, López-Bautista, and Bird (1996); for Veracruz, including Enmedio Reef—Huerta (1960a, b), Humm and Hildebrand (1962), Huerta and Garza Barrientos (1964), de la Campa de Guzmán (1965), Sánchez Rodríguez (1965), Rigby and McIntire (1966), Chávez, Hidalgo, and Sevilla (1970), Lot Helgueras (1971), Villalobos (1971), Chávez (1973), Sánchez Rodríguez, Flores Davis, and Ramírez Rodríguez (1975), Huerta, Chavez-Barrera, and Sanchez Rodriguez (1977), Novelo Retana (1978), Quintana Molina (1980), Sánchez Rodríguez (1980), Quintana Molina et al. (1981a, b), Mendoza González and Mateo-Cid (1985), Sobrino-Figueroa and Senties-Granados (1986), Quintana Molina (1991), Lehman and Tunnell (1992), Flores Davis (1993), Dreckmann and Pérez-Hernández (1994), González Fierro et al. (1994), Orozco Vega and Dreckmann (1995), Collado Vides and West (1996), Mateo-Cid, Mendoza-González, and Garcia (1996), Dreckmann and de Lara-Isassi (2000), Gurgel, Fredericq, and Norris (2003), Mateo-Cid, Mendoza-González, and Searles (2003), and Mateo-Cid and Pedroche (2004); for Tabasco—Dreckmann and de Lara-Isassi (2000); for Campeche—Huerta (1958, 1961), Huerta and Garza Barrientos (1964, 1966), Villalobos (1971), Orozco Vega and Dreckmann (1995), Ortega (1995), Mateo-Cid, Mendoza-González, and Galicia García (1996), Robledo, Freile-Peregrin, and Sanchez Rodríguez (2003), and Callejas Jiménez, Senties Granados, and Dreckmann (2005); for Yucatán, including Alacrán Reef—Kornicker et al. (1959), Taylor (1960), Huerta (1961), Kim (1964), Taylor (1972), Huerta, Mendoza González, and Mateo Cid (1987), Cheney (1988), Arellano-Guillermo and Serrano-Islas (1993), Robledo and Freile Peregrin (1997), Dreckmann (1998), Aguilar-Rosas et al. (2001), and Ortegón-Aznar, González-González, and Senties-Granados (2001); for Quintana Roo—Huerta and Garza Barrientos (1980). General lists for the Mexican Gulf of Mexico include Humm (1964), Earle (1972), Orozco Vega and Dreckmann (1995), González González et al. (1996), and Ortega, Godínez, and Garduño Solórzano (2001).

The main treatments for the seaweeds in the southeastern Gulf of Mexico are still based on collections from the Dry Tortugas by Taylor (1928), and recent subtidal collections made by Ballantine (1996). Major references for Cuba include Díaz Pifferer (1964), Vinogra-

dova (1975), Sosa (1977, 1985), Vinogradova and Sosa (1977), and Suárez (1973, 2005). Ecological works on seaweeds comprise Buesa (1977), González-Sansón and Berdayes (1981), de la Cruz (1982), Suárez and Cortés (1983), Areces (1989), Suárez (1989), Suárez, Gil, and Poseck (1996), Jiménez (1990), Jiménez and Alcolado (1990), Suárez and Ravelo (1996), Trelles, Suarez, and Collado-Vides (1997), Trelles, Suárez, and de la Guardia (2001), Aguilar et al. (2000), Guardia, González, and Trelles (2001), Zayas, Suárez, and Ocana (2002), Cabrera and Suárez (2003, 2005), Cabrera et al. (2004), Cabrera, Moreira, and Suárez (2004), Cabrera et al. (2005), Moreira, Suárez, and Cabrera (2004), Moreira, Cabrera, and Suárez (2005), and Valdivia et al. (2004).

Seaweed cultures in Cuba have been attempted on the red algal genera *Bryothamnion* (see Areces 1989), and *Gracilaria* and *Gracilariaopsis* (see Castellanos González, Leon, and Moreira 2003, Castellanos González, Sharp, and Leon 2003) to assess agar production and quality. The brown algal genera *Sargassum* and *Turbinaria* are cultivated for the extraction of alginates (Zúñiga and Suárez 1999). Green algae, such as *Ulva*, are harvested for food on rocky shores (Cano Mallo et al. 2005).

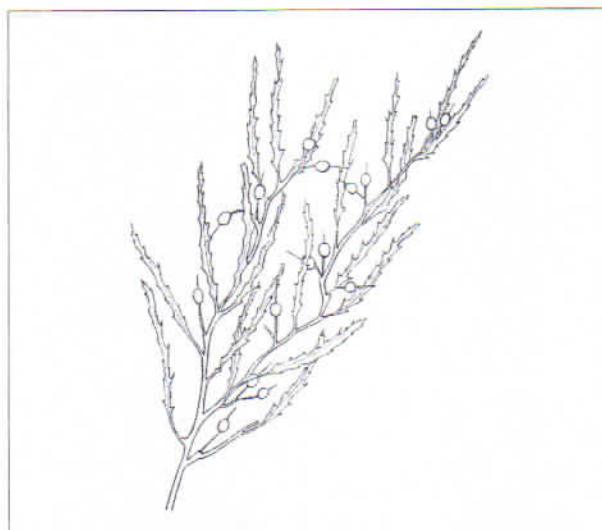

Seaweed species from the Gulf of Mexico have been used in molecular phylogenetic treatments, and in biogeographical and population genetic studies. Examples of green algae are included in Famá et al. (2002), of brown algae in Phillips and Fredericq (2000), and of red algae in Lin, Fredericq, and Hommersand (2001), Lin, Hommersand, and Fredericq (2004), Zuccarello and West (2002), Lin and Fredericq (2003), Gurgel and Fredericq (2004),

A green seaweed, *Ulva*. After Taylor 1954.

Gurgel, Fredericq, and Norris (2004a, b, c), Gavio and Fredericq (2005), and Gavio, Hickerson, and Fredericq (2005).

Since the 1954 "Bulletin 89" treatment of the seaweeds in the Gulf of Mexico, many regional studies have been conducted (see previous paragraphs). The checklist furnished here for Gulf of Mexico seaweeds represents a thorough review of predominantly peer-reviewed publications of regional species. The present study lists the macroalgal species alphabetically per family and indicates to which families the taxa belong. Families are grouped phylogenetically as much as possible. Records include information on habitat and distribution worldwide. In the past 35 years the systematics of the red, brown, and green seaweeds has changed significantly, and there has been the addition of species previously unreported from the Gulf of Mexico. The species binomials and authorship reported herein follow the rules of the International Code of Botanical Nomenclature and the Type Method as found in Silva (1952, 1972, 1980), Silva, Basson, and Moe (1996), and Wynne (2005). Online resources such as the Index Nominum Algarum (Silva 2007) and Algaebase (Guiry and Guiry 2007) databases provide information on the diversity of the groups worldwide.

A brown seaweed, *Sargassum*. After Taylor 1954.

## Abbreviations

All abbreviations for Habitat-Biology used in this checklist are given with their definitions following. Ecological group descriptors: ben = benthic; plk = planktonic; epi = epiphytic or epizoic on soft tissue; par = parasite; or = oyster reef; est = estuary. General depth/strata descriptors: bns = bay and nearshore; dr = drift; int = intertidal; oc = ocean; ofs = offshore; osp = oceanic surface and epipelagic; shw = shallow subtidal (from 3 to 10 m depth); subt = subtidal (from deeper than 10 m depth). Depths are for entire

range of the species. Substratum/biotic associations: hsb = hard substratum; sft = soft substrata (mud, sands, clays). Geographic distribution descriptors: Afr = Africa; AK = Alaska, U.S.A.; Am = American; Aust = Australia; Atl = Atlantic Ocean; Carib = Caribbean Sea; C = Central; CT = Connecticut, U.S.A.; E = East or eastern; Eur = Europe; Falkl = Falkland; FL = Atlantic Florida, U.S.A.; GoCA = Gulf of California; GMx = Gulf of Mexico; HI = Hawaii; I = Island; Isls = Islands; Mex = Mexico; NC = North Carolina, U.S.A.; New Zeal = New Zealand; N = North or northern; ne = northeastern Gulf; NW = Northwest; nw = northwestern Gulf; NY = New York, U.S.A.; Oc = ocean; Pac = Pacific; PNG = Papua New Guinea; se = southeastern Gulf; S = South or southern; SE = Southeast; SC = South Carolina, U.S.A.; SW = Southwest; sw = southwestern Gulf; trop = tropical; VA = Virginia, U.S.A.; W = West or western; Zeal = Zealand. Other descriptors: exc = except for.

The geographic range for each reported taxon listed here is a compilation from many published sources. Some categories have been included to denote a general distribution if a taxon is listed more than once in a geographic area. For example, SW Asia (India, Pakistan, Bahrain, Iran, Jordan, Kuwait, Levant States, Oman, the Philippines, Qatar, Saudi Arabia, Sri Lanka, Yemen), SE Asia (Indonesia, Vietnam, Burma, Malaysia), Europe (throughout N, W, and S), Atlantic Islands (Bermuda, Azores, Canary Islands, Cape Verde Islands, Madeira, Salvage Islands, Asencion Island), Africa (West, North, East, and South; thus, "W, E, & S Afr" indicates that the taxon has been reported from, for example, Ghana, Tanzania, and South Africa), Indian Ocean Islands (Aldabra, Seychelles, Andaman Islands, Maldives), tropical Pacific Islands (Hawaiian Islands, Micronesia, French Polynesia, Samoan Archipelago, Solomon Islands, Marshall Islands, Fiji, Chagos Archipelago, Diego Garcia Atoll, Réunion Island, Rodrigues Island) or Australia (West Australia includes Lord Howe Island).

### Acknowledgments

We thank Darryl Felder, Wes Tunnell, and David Camp for inviting us to contribute an updated taxonomic compilation of the published names of the seaweeds occurring in the Gulf of Mexico. We also thank Darryl Felder for inviting us to participate in collecting cruises, and Emma Hickerson and G. P. Schmahl, Flower Garden Banks National Marine Sanctuary (NOAA), for facilitating algal collecting inside the Sanctuary and for their continuous support. We thank Bob Sims, Smithsonian Institution, for forwarding valuable historical literature, as well as the many col-

lectors who have sent us seaweed samples from throughout the Gulf of Mexico. The National Science Foundation, Biodiversity Surveys and Inventories grant DEB-0315995, made it possible to gain a better understanding of seaweed diversity throughout the Gulf of Mexico. Additional support from the U.S. Department of Energy (DE-FG02-97ER12220), NOAA's National Undersea Research Center (NA96RU-016), a NOAA grant facilitated by Elaine Hoagland (ITIS), a PSA Grant-in-Aid of Research, and the J. Bennett Johnston Foundation is greatly acknowledged. We thank Kim Yates, U.S. Geological Survey, St. Petersburg, Florida, for her collaboration with the Tampa Bay seagrass epiphyte project (USGS-00CRAG00035), and the crews of the R/V *Pelican* (LUMCON), M/V *Rinn*, and the R/V *Gunther* (NOAA) for technical support. Natalia Arakaki, Constanza Ehrenhaus, Daniela Gabriel, Brigitte Gavio, Showe-Mei Lin, Juan Lopez-Bautista, Naomi Phillips, William Schmidt, Boo Yeon Won, and Bryan Wysor are greatly acknowledged for their close phycological research affiliations with U.L.-Lafayette over the years. C. M. thanks the Comisión de Operación y Fomento de Actividades Académicas del I.P.N. for fellowship support. Many algal specimens that were investigated in the students' doctoral dissertations were based on these recent Gulf of Mexico collections.

Division: Rhodophyta		
	<i>Acrochaetium crassipes</i>	= <i>Acrochaetium microscopicum</i>
	<i>Acrochaetium sagraeanum</i>	= <i>Acrochaetium secundatum</i>
	<i>Galaxaura obtusata</i>	= <i>Dichotomaria obtusata</i>
	<i>Acrochaetium sargassi</i>	= <i>Acrochaetium hallanicum</i>
	<i>Acrochaetium seriatum</i>	= <i>Acrochaetium hypnea</i>
	<i>Acrochaetium thuretii</i>	= <i>Acrochaetium savianum</i>
	<i>Acrochaetium trifilum</i>	= <i>Acrochaetium microscopicum</i>
	<i>Acrochaetium virgatum</i>	= <i>Acrochaetium secundatum</i>
	<i>Agardhiella baileyi</i>	= <i>Agardhiella subulata</i>
	<i>Agardhiella tenera</i>	= <i>Agardhiella subulata</i>
	<i>Aglaothamnion pseudobyssoides</i>	= <i>Aglaothamnion halliae</i>
	<i>Amphiroa rigida</i> var. <i>antillana</i>	= <i>Amphiroa rigida</i>
	<i>Antithamnion lherminieri</i>	= <i>Antithamnion antillanum</i>
	<i>Asterocystis ornata</i>	= <i>Chroodactylon ornatum</i>
	<i>Asterocystis ramosa</i>	= <i>Chroodactylon ornatum</i>
	<i>Audouinella affinis</i>	= <i>Acrochaetium affine</i>
	<i>Audouinella antillarum</i>	= <i>Acrochaetium antillarum</i>
	<i>Audouinella bispora</i>	= <i>Acrochaetium bisporum</i>
	<i>Audouinella crassipes</i>	= <i>Acrochaetium microscopicum</i>
	<i>Audouinella flexuosa</i>	= <i>Acrochaetium flexuosum</i>
	<i>Audouinella hoytii</i>	= <i>Acrochaetium hoytii</i>
	<i>Audouinella hypnea</i>	= <i>Acrochaetium hypnea</i>
	<i>Audouinella microscopicica</i>	= <i>Acrochaetium microscopicum</i>
	<i>Audouinella pulchella</i>	= <i>Acrochaetium pulchellum</i>
	<i>Audouinella robusta</i>	= <i>Acrochaetium robustum</i>
	<i>Audouinella secundata</i>	= <i>Acrochaetium secundatum</i>
	<i>Audouinella virgulata</i>	= <i>Acrochaetium secundatum</i>
	<i>Bangia atropurpurea</i>	= <i>Bangia fuscopurpurea</i>
	<i>Bostrychia binderi</i>	= <i>Bostrychia tenella</i>
	<i>Bostrychia pinnata</i>	= <i>Bostrychia calliptera</i>
	<i>Bostrychia rivularis</i>	= <i>Bostrychia tenella</i>
	<i>Brongniartella mucronata</i>	= <i>Micropeuce mucronata</i>
	<i>Calaconema secundatum</i>	= <i>Acrochaetium secundatum</i>
	<i>Callithamnion byssoides</i>	= <i>Aglaothamnion halliae</i>
	<i>Callithamnion cordatum</i>	= <i>Aglaothamnion cordatum</i>
	<i>Callithamnion halliae</i>	= <i>Aglaothamnion halliae</i>
	<i>Callithamnion herveyi</i>	= <i>Aglaothamnion herveyi</i>
	<i>Callithamnion pseudobyssoides</i>	= <i>Aglaothamnion halliae</i>
	<i>Callithamnion roseum</i>	= <i>Aglaothamnion roseum</i>
	<i>Catenella repens</i>	= <i>Catenella caespitosa</i>
	<i>Centroceras clavulatum</i>	= <i>Centroceras</i> sp.
	<i>Ceramium byssoides</i>	= <i>Ceramium flaccidum</i>
	<i>Ceramium fastigiatum</i> f. <i>flaccidum</i>	= <i>Ceramium cimbricum</i>
	<i>Ceramium fastigiatum</i> var. <i>flaccidum</i>	= <i>Ceramium flaccidum</i>
	<i>Ceramium gracillimum</i>	= <i>Ceramium flaccidum</i>
	<i>Ceramium rubrum</i>	= <i>Ceramium virgatum</i>
	<i>Ceramium strictum</i>	= <i>Ceramium deslongchampsii</i>
	<i>Ceramium tenuissimum</i>	= <i>Ceramium diaphanum</i>
	<i>Ceramium vagabundum</i>	= <i>Ceramium vagans</i>
	<i>Chantransia flexuosa</i>	= <i>Acrochaetium flexuosum</i>
	<i>Chondria tenuissima</i>	= <i>Chondria capillaris</i>
	<i>Coelarthrrum albertesii</i>	= <i>Coelarthrrum cliftonii</i>
	<i>Corallina cubense</i>	= <i>Haliptilon cubense</i>

## List of reported synonymous taxa. (continued)

Component subgroups	Reported former name	Current species name
	<i>Corallina subulata</i>	= <i>Haliptilon subulatum</i>
	<i>Cryptopleura fimbriata</i>	= <i>Cryptopleura ramosa</i>
	<i>Cyclospora curtissiae</i>	= <i>Carpoblepharis curtissiae</i>
	<i>Dasya arbuscula</i>	= <i>Dasya hutchinsiae</i>
	<i>Dasya pedicellata</i>	= <i>Dasya baillouviana</i>
	<i>Dasyopsis antillarum</i>	= <i>Dasya antillarum</i>
	<i>Dermatolithon pustulatum</i>	= <i>Lithophyllum pustulatum</i>
	<i>Erythrocladia recondita</i>	= <i>Erythrocladia endophloea</i>
	<i>Erythrocladia subintegra</i>	= <i>Sahlingia subintegra</i>
	<i>Erythrocladia vagabunda</i>	= <i>Erythrocladia endophloea</i>
	<i>Erythropeltis subintegra</i>	= <i>Sahlingia subintegra</i>
	<i>Eucheuma acanthocladum</i>	= <i>Meristotheca gelidum</i>
	<i>Eucheuma echinocarpum</i>	= <i>Meristotheca echinocarpa</i>
	<i>Eucheuma gelidum</i>	= <i>Meristiella gelidum</i>
	<i>Eupogodon antillarum</i>	= <i>Dasya antillarum</i>
	<i>Falkenbergia</i> sp.	= Falkenbergia-stage of <i>Asparagopsis taxiformis</i>
	<i>Fauchea peltata</i>	= <i>Asteromenia peltata</i>
	<i>Fosliella affinis</i>	= <i>Neogoniolithon affine</i>
	<i>Fosliella atlantica</i>	= <i>Lithoporella atlantica</i>
	<i>Fosliella farinosa</i>	= <i>Hydrolithon farinosum</i>
	<i>Fosliella lejolisii</i>	= <i>Pneophyllum fragile</i>
	<i>Galaxaura cylindrica</i>	= <i>Tricleocarpa cylindrica</i>
	<i>Galaxaura fragilis</i>	= <i>Tricleocarpa fragilis</i>
	<i>Galaxaura marginata</i>	= <i>Dichotomaria marginata</i>
	<i>Galaxaura oblongata</i>	= <i>Tricleocarpa fragilis</i>
	<i>Galaxaura stellifera</i>	= <i>Tricleocarpa fragilis</i>
	<i>Galaxaura subverticillata</i>	= <i>Galaxaura rugosa</i>
	<i>Gelidium corneum</i>	= <i>Gelidium spinosum</i>
	<i>Gelidium rigidum</i>	= <i>Gelidiella acerosa</i>
	<i>Gelidiella pannosa</i>	= <i>Parviphycus tenuissimus</i>
	<i>Gigartina acicularis</i>	= <i>Chondracanthus acicularis</i>
	<i>Goniolithon accretum</i>	= <i>Neogoniolithon accretum</i>
	<i>Goniolithon affine</i>	= <i>Neogoniolithon affine</i>
	<i>Goniolithon mamillare</i>	= <i>Neogoniolithon mammillare</i>
	<i>Goniolithon soluble</i>	= <i>Neogoniolithon soluble</i>
	<i>Goniolithon spectabile</i>	= <i>Neogoniolithon spectabile</i>
	<i>Goniolithon strictum</i>	= <i>Neogoniolithon strictum</i>
	<i>Goniothrichum alsidii</i>	= <i>Stylonema alsidii</i>
	<i>Gracilaria armata</i>	= <i>Gracilaria apiculata</i>
	<i>Gracilaria armata</i>	= <i>Gracilaria secunda</i>
	<i>Gracilaria caudata</i>	= <i>Hydropuntia caudata</i>
	<i>Gracilaria compressa</i>	= excluded name
	<i>Gracilaria confervoides</i>	= excluded name
	<i>Gracilaria cornea</i>	= <i>Hydropuntia cornea</i>
	<i>Gracilaria cylindrica</i>	= <i>Gracilaria blodgettii</i>
	<i>Gracilaria damaecornis</i>	= <i>Hydropuntia cornea</i>
	<i>Gracilaria debilis</i> , in part	= <i>Hydropontia crassissima</i>
	<i>Gracilaria divaricata</i>	= excluded name
	<i>Gracilaria ferox</i>	= <i>Gracilaria cervicornis</i>
	<i>Gracilaria foliifera</i>	= <i>Gracilaria tikvahiae</i>
	<i>Gracilaria lacinulata</i>	= <i>Gracilaria isabellana</i>
	<i>Gracilaria mammillaris</i>	= <i>Gracilaria flabelliformis</i>
	<i>Gracilaria verrucosa</i>	= <i>Gracilaria caudata</i>

(continued)

**List of reported synonymous taxa. (continued)**

Component subgroups	Reported former name	Current species name
	<i>Gracilaria verrucosa</i>	= <i>Gracilaria secunda</i>
	<i>Gracilariopsis costaricensis</i>	= <i>Gracilariopsis tenuifrons</i>
	<i>Gracilariopsis lemaneiformis</i>	= <i>Gracilariopsis tenuifrons</i>
	<i>Gracilariopsis sjoestedtii</i>	= <i>Gracilariopsis tenuifrons</i>
	<i>Gratelouphia filicina</i>	= <i>Gratelouphia</i> sp.
	<i>Griffithsia barbata</i>	= <i>Anotrichium barbatum</i>
	<i>Griffithsia tenuis</i>	= <i>Anotrichium tenue</i>
	<i>Halymenia agardhii</i>	= <i>Sebdenia flabellata</i>
	<i>Halymenia ligulata</i>	= <i>Halarachnion ligulata</i>
	<i>Halymenia pseudofloresia</i>	= <i>Halymenia floresia</i>
	<i>Heteroderma lejolisii</i>	= <i>Pneophyllum fragile</i>
	<i>Heterosiphonia wurdemannii</i>	= <i>Heterosiphonia crispedia</i>
	<i>Hildenbrandia prototypus</i>	= <i>Hildenbrandia rubra</i>
	<i>Hypnea alopecuroides</i>	= <i>Hypnea musciformis</i>
	<i>Hypnea cervicornis</i>	= <i>Hypnea spinella</i>
	<i>Hypnea cornuta</i>	= <i>Hypnea valentiae</i>
	<i>Kallymenia limminghei</i>	= "Kallymenia limminghei"
	<i>Kylinia crassipes</i>	= <i>Acrochaetium microscopicum</i>
	<i>Kylinia pulchella</i>	= <i>Acrochaetium pulchellum</i>
	<i>Kylinia robusta</i>	= <i>Acrochaetium robustum</i>
	<i>Kylinia secundata</i>	= <i>Acrochaetium secundatum</i>
	<i>Laurencia corallopsis</i>	= <i>Chondrophycus corallopsis</i>
	<i>Laurencia gemmifera</i>	= <i>Chondrophycus gemmifera</i>
	<i>Laurencia papillosa</i>	= <i>Chondrophycus papillosa</i>
	<i>Laurencia poiteauii</i>	= <i>Chondrophycus poiteauii</i>
	<i>Liagora decussata</i>	= <i>Liagora albicans</i>
	<i>Liagora dendroidea</i>	= <i>Ganonema dendroidea</i>
	<i>Liagora elongata</i>	= <i>Ganonema farinosum</i>
	<i>Liagora farinosum</i>	= <i>Ganonema farinosum</i>
	<i>Liagora maxima</i>	= <i>Liagora albicans</i>
	<i>Liagora mucosa</i>	= <i>Ganonema dendroidea</i>
	<i>Liagora pedicellata</i>	= <i>Trichogloeopsis pedicellata</i>
	<i>Liagora pinnata</i>	= <i>Ganonema pinnatum</i>
	<i>Liagora valida</i>	= <i>Titanophycus validus</i>
	<i>Lithophyllum bermudense</i>	= <i>Titanoderma bermudense</i>
	<i>Lithophyllum pustulatum</i>	= <i>Titanoderma pustulatum</i>
	<i>Lithothamnion incertum</i>	= <i>Mesophyllum incertum</i>
	<i>Lithothamnion syntrophicum</i>	= <i>Mesophyllum syntrophicum</i>
	<i>Lomentaria uncinata</i>	= <i>Lomentaria baileyana</i>
	<i>Lophosiphonia saccorhiza</i>	= <i>Polysiphonia saccorhiza</i>
	<i>Lophosiphonia scopulorum</i>	= <i>Polysiphonia scopulorum</i>
	<i>Meristella gelidium</i>	= <i>Meristotheca gelidium</i>
	<i>Mesothamnion caribaeum</i>	= <i>Pleonosporium caribaeum</i>
	<i>Nemalion multifidum</i>	= <i>Nemalion helminthoides</i>
	<i>Nemalion schrammii</i>	= <i>Liagoropsis schrammii</i>
	<i>Neogoniolithon solubile</i>	= <i>Neogoniolithon fosliei</i>
	<i>Nitophyllum punctatum</i>	= <i>Nitophyllum adhaerens</i>
	<i>Polysiphonia ferulacea</i>	= <i>Neosiphonia ferulacea</i>
	<i>Polysiphonia flaccidissima</i>	= <i>Neosiphonia flaccidissima</i>
	<i>Polysiphonia gorgoniae</i>	= <i>Neosiphonia gorgoniae</i>
	<i>Polysiphonia sertularioides</i>	= <i>Neosiphonia flaccidissima</i>
	<i>Polysiphonia sphaerocarpa</i>	= <i>Neosiphonia sphaerocarpa</i>
	<i>Polysiphonia tepida</i>	= <i>Neosiphonia tepida</i>

## List of reported synonymous taxa. (continued)

Component subgroups	Reported former name	Current species name
	<i>Porolithon boergesenii</i>	= <i>Hydrolithon boergesenii</i>
	<i>Porolithon pachydermum</i>	= <i>Hydrolithon pachydermum</i>
	<i>Porphyra atropurpurea</i>	= <i>Porphyra leucosticta</i>
	<i>Prionitis pterocladina</i>	= <i>Grateloupia pterocladina</i>
	<i>Pseudotetraspora antillarum</i>	= <i>Pseudotetraspora marina</i>
	<i>Pterocladia americana</i>	= <i>Gelidium americanum</i>
	<i>Pterocladia bartlettii</i>	= <i>Pterocladiella bartlettii</i>
	<i>Rhabdonia ramosissima</i>	= <i>Agardhiella ramosissima</i>
	<i>Searlesia subtropica</i>	= <i>Polyneura subtropica</i>
	<i>Solieria tenera</i>	= <i>Agardhiella subulata</i>
	<i>Spermothamnion gorgonea</i>	= <i>Tiffaniella gorgonea</i>
	<i>Spermothamnion speluncarum</i>	= <i>Ptilothamnion speluncarum</i>
	<i>Spermothamnion turneri</i>	= <i>Spermothamnion repens</i>
	<i>Spongites absimile</i>	= <i>Lithophyllum absimile</i>
	<i>Spyridia acuelata</i>	= <i>Spyridia hypnoides</i>
	<i>Trichogloea jadinii</i>	= <i>Trichogloea requienii</i>
	<i>Trichogloea papenfussii</i>	= <i>Trichogloea requienii</i>
	<i>Vidalia obtusiloba</i>	= <i>Osmundaria obtusiloba</i>
Division: Chlorophyta		
	<i>Acetabularia polyphysoides</i>	= <i>Parvocaulis polyphysoides</i>
	<i>Acetabularia pusilla</i>	= <i>Parvocaulis pusilla</i>
	<i>Acicularia schenckii</i>	= <i>Acetabularia schenckii</i>
	<i>Acrochaete viridis</i>	= <i>Entocladia viridis</i>
	<i>Bryobesia cylindricarpa</i>	= <i>Bryobesia johannae</i>
	<i>Bryopsis duchassaignii</i>	= <i>Trichosolen duchassaignii</i>
	<i>Bryopsis pennata</i> var. <i>secunda</i>	= <i>Bryopsis pennata</i>
	<i>Caulerpa ambigua</i>	= <i>Caulerella ambigua</i>
	<i>Caulerpa crassifolia</i>	= <i>Caulerpa mexicana</i>
	<i>Caulerpa cupressoides</i> var. <i>elegans</i>	= <i>Caulerpa cupressoides</i>
	<i>Caulerpa cupressoides</i> var. <i>flabellata</i>	= <i>Caulerpa cupressoides</i>
